Abstract. We present VLA and MERLIN monitoring data of the JVAS gravitational lens system B1030+074. The system was monitored with the VLA from February 1998 to October 1998 at 8.4-GHz during which the VLA was at its A, BnA and B configuration. The 47 epochs of observations have an average spacing of approximately 5 days. Ten MERLIN snapshots were obtained in the L-band (1.7 GHz) during the months of April, May and June 1998. Preliminary light curves of the two components of the lens system obtained from the VLA data indicate that during the period of the monitoring the A flux density showed a steady decrease. No changes are observed in the B light curve.

1. Introduction

B1030+074 was discovered during the course of the Jodrell-Bank VLA Astrometric Survey (JVAS; Patnaik et al. 1992; Browne et al. 1998, Wilkinson et al. 1998) which is a survey of flat-spectrum radio sources with the main purpose to search for gravitational lens systems. B1030+074 consists of two components separated by 1.56 arcseconds with a flux ratio that seems to be changing with both time and frequency (Xanthopoulos et al. 1998). Keck spectra have revealed a redshift of 0.599 for the lensing galaxy and of 1.535 for the background source. An initial model of this system has yielded a time delay of $156/h_{50}$ days while radio observations (EVN, MERLIN, VLBA, VLA) give a flux density ratio for the two components that ranges from 12.0 to 18.8. So since we already know the redshifts of the system and we are in the processs of improving the mass

model of the lens (through VLBA observations; Xanthopoulos et al. 2000, in preparation) and also since the system has already shown signs of variability we embarqued on two monitoring programs with the main purpose to confirm the variable nature of the source.

2. The Data and Preliminary Results

The initial flux and phase calibration of the 47 epochs is done with AIPS while the mapping and modelfitting was performed within DIFMAP. From this we obtained the light curves for components A and B of the lens system.

Fig. 1 shows the preliminary light curves of B1030+074. We have divided each light curve by the average flux density of each component. The light curve of component A shows a steady decrease in flux density with epoch while we see no changes in the B light curve. Further analysis and interpretation of the results is underway.
